1.0 SRS Revision

1.1 Use Case 1: [Insert Use Case Name/ID]

1.1 .1 As-Is (Original Version)

From Section 3.2.3.1 Normal Flow:
Step 1: Customer selects Withdraw Funds from the interfac.
Step 8: Etiqa System authenticates the request via MFA/PIN
Step 13: Etiqa System displays a success message to the Customer

1.1.2 To-Be (Revised Version)

(Paste the corrected text here. Highlight the changes you made.)

Step 1: Customer selects the (**Withdraw**) icon from the Quick Actions menu on the Dashboard
Step 8: Etiqa System authenticates the request via 6-digit Security PIN or Biometric Authentication (Face ID/Fingerprint)
Step 8a (Exception Handling): If authentication fails or times out the system displays a Verification Failed error and provides a **Try Again** option.
Step 13: Etiqa System displays a "Withdrawal Successful" digital receipt containing the Reference ID, Date, and Status.

2.0 Change Justification Analysis

2.1 Prototype Analysis

During the development of the high-fidelity mock-up (specifically the **Authentication Screen** and **Dashboard**), the visualization process revealed distinct usability constraints that the text-based SRS missed.

1. **Visual Space:** On the Dashboard, the label "Withdraw Funds" was visually too long for the button size. The prototype revealed that "Withdraw" is cleaner and sufficient.
2. **Security Specificity:** The original SRS used the generic term "MFA". However, when designing the security screen, it became clear that for a mobile app, **Biometrics (FaceID)** is the standard expected behavior, not just a generic MFA.
3. **Error Handling:** The static SRS did not account for what happens if the user presses "Back" during the "Connecting..." phase. The prototype flow required us to design a specific **"Transaction Failed"** screen to handle this interruption safely.

2.2 Necessity of Correction

These corrections are necessary to align the Business Logic with the User Interface Reality.

4. Changing "MFA" to "PIN/Biometrics" is critical for the development team to know exactly which APIs to call (Native Biometric API vs. SMS Gateway).

5. Defining the "Withdrawal Successful" receipt in detail is necessary to satisfy Requirement FR-UC-009-04 (Download Receipt), which requires specific data fields (Ref ID) to be visible.

2.3 Impact Analysis

If the SRS remained incorrect (As-Is):

6. Development Risk: Backend developers might implement an SMS-based OTP system for Step 8, while the Frontend developers build a Biometric screen. This would cause a critical Integration Failure.
7. User Confusion: If the documentation refers to "Withdraw Funds" but the app says "Withdraw", the Quality Assurance (QA) team might flag this as a bug during testing, causing unnecessary delays.
8. Security Gap: Without defining the "Transaction Failed" exception flow added in the prototype, the system might leave a transaction in a "Pending" state indefinitely if a user interrupts the connection, leading to potential data inconsistency.

Appendix A: List of Prompt

Prompt 1: "Check the consistency of the 'Withdraw' button name between the SRS and the Design."

- [Insert Screenshot of me telling you to change 'Withdraw Fund' to 'Withdraw Funds']

Prompt 2: "Define the flow for the 'Connecting to Bank' screen and handling user interruption."

- [Insert Screenshot of our discussion about the 'Back' button logic]

Prompt 3: "Suggest the correct terminology for the Authentication screen (PIN vs OTP) based on the SRS."
